Table of contents

- ▶ Why IP?
 - ▶ Motivations
- ▶ How IP?
 - ▶ Architecture
 - ▶ Addressing
 - ▶ Routing
- ▶ When IP?
 - ▶ ARP
 - ▶ DHCP

Why IP?

- ▶ Many different network access technologies, reflecting many different needs
 - ▶ Wireless technologies: 3G, Wi-Fi, Wi-Max, ...
 - ▶ High speed transfers with cable: copper, optical fibers, ...
 - ▶ Low energy consumption: Bluetooth, Zigbee, NFC, ...
- ▶ And what if all these technologies must talk to each other?
 - ▶ The Internet Protocol (IP) acts as a common language for data transfer between different *hosts*, independently from the network technology in use

Internet Protocol

- ▶ Internet Protocol mission: allow hosts on different network to interoperate, disregarding the specific network technology adopted on each network
- ▶ Standardized in 1981 on RFC 791
(<http://www.ietf.org/rfc/rfc791.txt>)

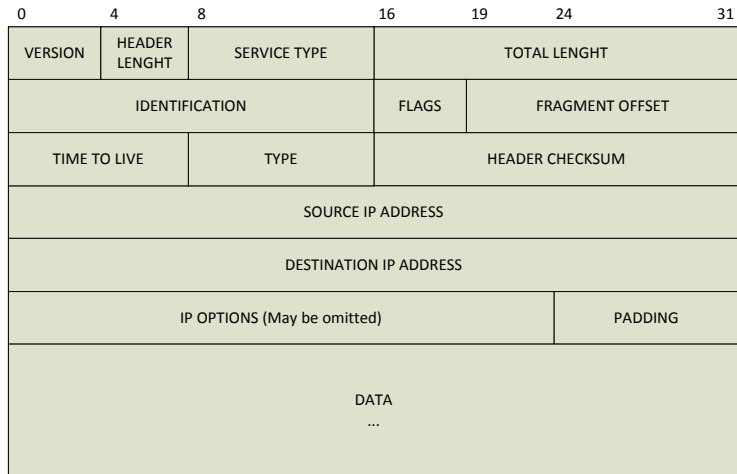

A simple IP architecture

- ▶ All hosts use IP protocol to exchange data
- ▶ All data is exchanged using a specific PDU called IP datagram (packet)

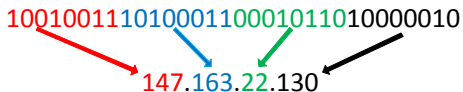

IP datagram format

IP address

- ▶ Each host over the network has an IP address to identify itself
 - ▶ 32 bit long
 - ▶ Unique inside a single IP network
 - ▶ Identifies an interface (on a host, on a router)
- ▶ Often represented by dotted notation
 - ▶ 4 bytes separated by a point
 - ▶ Just for human convenience!

Grouping related hosts

- ▶ A single *network* is composed by *hosts*
- ▶ Internet is an inter-network
 - ▶ Used to connect *networks* together
 - ▶ Needs a way to address networks
- ▶ Solution: subnetting and IP prefixes

Subnetting and IP prefixes

- ▶ A subnet mask divides a single network in *subnets*
 - ▶ More flexibility in huge network management
 - ▶ Hierarchical structure inside the same network
- ▶ Hosts inside a single subnet share the same network part
 - ▶ Division given by the subnet
 - ▶ Each IP has a different host part

IP addresses

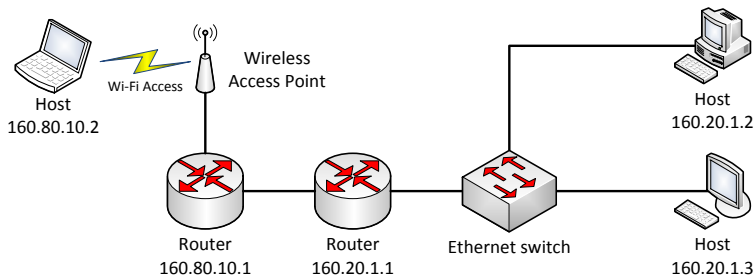

- ▶ In each subnet there are two reserved addresses
 - ▶ Host part with all 0 is the *network address*
 - ▶ Host part with all 1 is the *broadcast address*
- ▶ Example: 192.168.100.7/24
 - ▶ Network address: 192.168.100.0
 - ▶ Broadcast address: 192.168.100.255
- ▶ Routers must have an IP address and a netmask for each interface they have

Subnets

- ▶ Every host inside a LAN belongs to an **IP subnet**
- ▶ In each subnet, addresses belong to a specific range:
 - ▶ The first part of the address (network part) is the same for all the hosts
 - ▶ The second part (host part) must be different for all the host

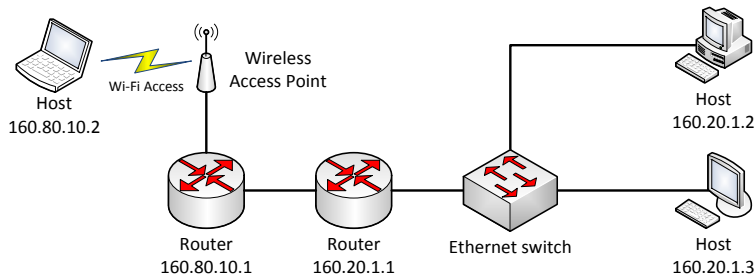

How IP? Architecture

- ▶ Communication among IP hosts is carried using **IP packets**
 - ▶ IP packet is composed by an **IP header** and an **IP payload**
 - ▶ Source and destination IP addresses are specified inside the IP header
- ▶ Networks are connected using at least one **router**
 - ▶ Forwards packets depending on the packet destination address

How IP? Architecture - Example

What happens if host 160.80.10.2 want to communicate with host 160.20.1.3?

How IP? Architecture - Example

- ▶ Host 160.80.10.2 generates an IP packet
- ▶ The IP packet is sent to the router 160.80.10.1 using a specific LAN technology.

How IP? Architecture - Example

- ▶ The router 160.80.10.1 reads the IP header
- ▶ The packet is forwarded to the **next hop**, according to the internal **routing table**

How IP? Architecture - Example

- ▶ The router 160.20.1.1 reads the IP header
- ▶ The packet is forwarded to the **next hop**, according to the internal **routing table**

Communication is independent from the underlying technology!

Some practice: traceroute

Exploiting time exceeded

Send packets with $TTL = 1, 2, \dots$ and record source of time exceeded message

- ▶ Linux & OSX: `traceroute <host>`
- ▶ Windows: `tracert <host>`

Routing

- ▶ All routers forward IP packets according to a **routing table**
- ▶ Each line has
 - ▶ A destination network...
 - ▶ ... its subnet mask...
 - ▶ ... and the next hop (where to send an incoming packet)

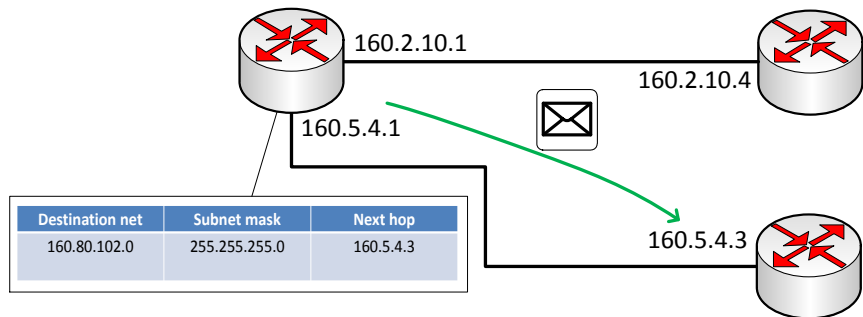

Destination network	Subnet mask	Next hop
160.80.102.0	255.255.255.0	160.5.4.3

Routing rule: if the destination IP address of a packet matches a specific destination network, route the packet to the related next hop

Routing example

Routing example

Routers

- ▶ Routing tables can be filled
 - ▶ Manually
 - ▶ Automatically, by routing protocol (e.g. RIP, BGP, OSPF, ...)
 - ▶ Mixed
- ▶ IP addressing/routing depends on the place

Longest prefix match and default gateways

Destination network	Subnet mask	Next hop
160.80.102.0	255.255.255.0	160.1.2.1
160.80.0.0	255.255.0.0	160.1.2.10

Where to send a packet with destination address 160.80.102.3?

- ▶ **Longest prefix match:** if more entries are matched, apply the rule with the greater subnet mask

Destination network	Subnet mask	Next hop
0.0.0.0	0.0.0.0	1.2.3.4

All those 0s???

- ▶ **Default gateway:** always matched, but not always used!

Some practice: viewing the routing table

- ▶ Windows: `netstat -rn`
- ▶ Linux & OSX: `route -n`

The bond between LAN and IP

IP packets are sent to the physical network interface by encapsulating them in a datalink frame using datalink addresses (operation performed hop-by-hop)

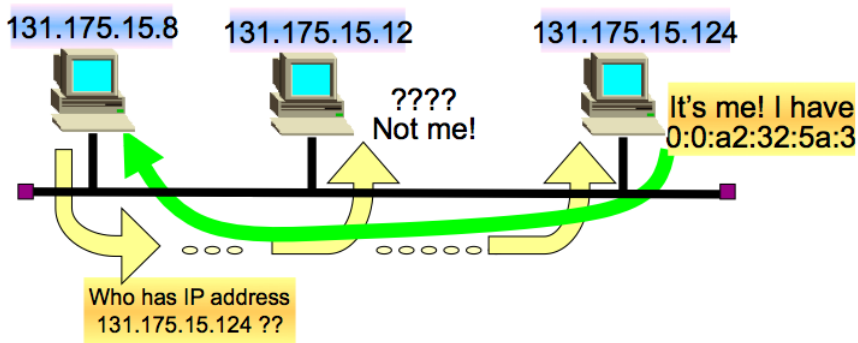

- ▶ Datalink addresses (MAC): local on a specific subnet
- ▶ IP addresses: globally assigned on the Internet
- ▶ How to dynamically map IP addresses to datalink addresses without any a-priori knowledge?
 - ▶ Solution: **ARP** (Address Resolution Protocol)

The solution: ARP

- ▶ Dynamic mapping
 - ▶ not a concern for application, user and system administrator
- ▶ Not layer 2 nor layer 3 protocol
- ▶ Need datalink with broadcasting capability
- ▶ ARP NOT strictly necessary
 - ▶ There may be IP-MAC mapping

The ARP idea

ARP features and practice

- ▶ Some ARP features
 - ▶ Stateless protocol: request-response
 - ▶ Send broadcast request
 - ▶ Receive unicast response
 - ▶ *Soft-state entries*: storage of IP datalink entries in a cache (the **ARP cache**) for a fixed amount of time
- ▶ Some practice
 - ▶ Windows, Linux and OSX: `arp -a`

Getting an IP address

How can an interface be configured?

- ▶ Manual configuration
- ▶ Automatically assigned, permanent random IP address
- ▶ Dynamically assigned
- ▶ Auto-assigned

DHCP

Autoconfiguration can be achieved via **DHCP**
(**D**ynamic **H**ost **C**onfiguration **P**rotocol)

- ▶ Goal of DHCP: **full** configuration of a host:
 - ▶ IP address, subnet mask, gateway IP address
 - ▶ DNS server
 - ▶ SMTP server
 - ▶ xyz server (extensible protocol!)
- ▶ Client/Server model (via UDP datagrams)

When IP? DHCP (3)
